# Statistics (TransAlign)

## Alignment statistics for: A1

Summary for input: K\_RMXA1v2.accepted\_hits.bam

\*\*\*

\*\*\* Fraction of reads mapped to the synthetic and experimental chromosomes

\*\*\*

Unmapped: 0 reads  
Synthetic: 36484961 (76.1291%) reads  
Experiment: 11440146 (23.8709%) reads  
Dilution: 0.761291

\*\*\*

\*\*\* Reference annotation (Synthetic)

\*\*\*

Supplied: ATR001.v032.gtf

Synthetic: 1190 exons  
Synthetic: 1028 introns  
Synthetic: 149219 bases

\*\*\*

\*\*\* Reference annotation (Experiment)

\*\*\*

Supplied: GeneCodeChr1.gtf

Experiment: 106882 exons  
Experiment: 89631 introns  
Experiment: 12073481 bases

\*\*\*

\*\*\* User Alignments

\*\*\*

Split reads (Synthetic): 85464855 reads  
Non-split reads (Synthetic): 32195352 reads  
Covered bases (Synthetic): 161775 bases

Split reads (Experiment): 4116941 reads  
Non-split reads (Experiment): 1488979 reads  
Covered bases (Experiment): 15859943 bases

\*\*\*

\*\*\* The following statistics are computed at the exon, intron and base level.

\*\*\*

\*\*\* Please refer to the online documentation at [www.sequin.xyz](http://www.sequin.xyz) for more details.

## Statistics (Gene Expression)

### Pooled scatter plot for gene expression

The pooled scatter plot shows the expected abundance against measured abundance on the logarithm scale for all the replicates. This is done by plotting the average and standard deviation. The line is the fitted linear regression with 95% confidence interval drawn in black. A high  $R^2$  is desirable; the higher it is, the more accurate the gene expression experiment is.

## Gene expression summary

Summary for input: /Users/tedwong/Desktop/K\_562/Cufflinks/A1/genes.fpk\_tracking,/Users/tedwong/Desktop

\*\*\*

\*\*\* The statistics are shown in arithmetic average and standard deviation. For example,  
\*\*\*  $5.12 \pm 0.52$  has an arithmetic average of 5.12 and standard deviation 0.52.

\*\*\*

\*\*\*

\*\*\* Fraction of genes for synthetic and experiment relative to all genes detected in the input file  
\*\*\*

Synthetic:  $74.5 \pm 0.547723$  ( $0.00122844 \pm 9.00928e-06\%$ )

Experiment:  $60571.5 \pm 0.547723$  ( $0.998772 \pm 9.00928e-06\%$ )

\*\*\*

\*\*\* Reference annotation (Synthetic)

\*\*\*

File: /Users/tedwong/Desktop/K\_562/ATR001.v032.gtf

Reference:  $76 \pm 0$  gene

Detected:  $72.5 \pm 0.547723$  gene

\*\*\*

\*\*\* Please refer to the online documentation for more details on the regression statistics.

\*\*\*

\*\*\* Correlation: Pearson's correlation

## Gene expression scatter plot for: A1

The scatter plot shows the relationship between expected abundance against measured abundance on the logarithm scale for a single replicate. The line is the fitted linear regression with 95% confidence interval drawn in black. A high  $R^2$  is desirable; the higher it is, the more accurate the gene expression experiment is.

## Gene expression statistics for: A2

### Gene expression scatter plot for: B3

The scatter plot shows the relationship between expected abundance against measured abundance on the logarithm scale for a single replicate. The line is the fitted linear regression with 95% confidence interval drawn in black. A high  $R^2$  is desirable; the higher it is, the more accurate the gene expression experiment is.

## Statistics (Isoform Expression)

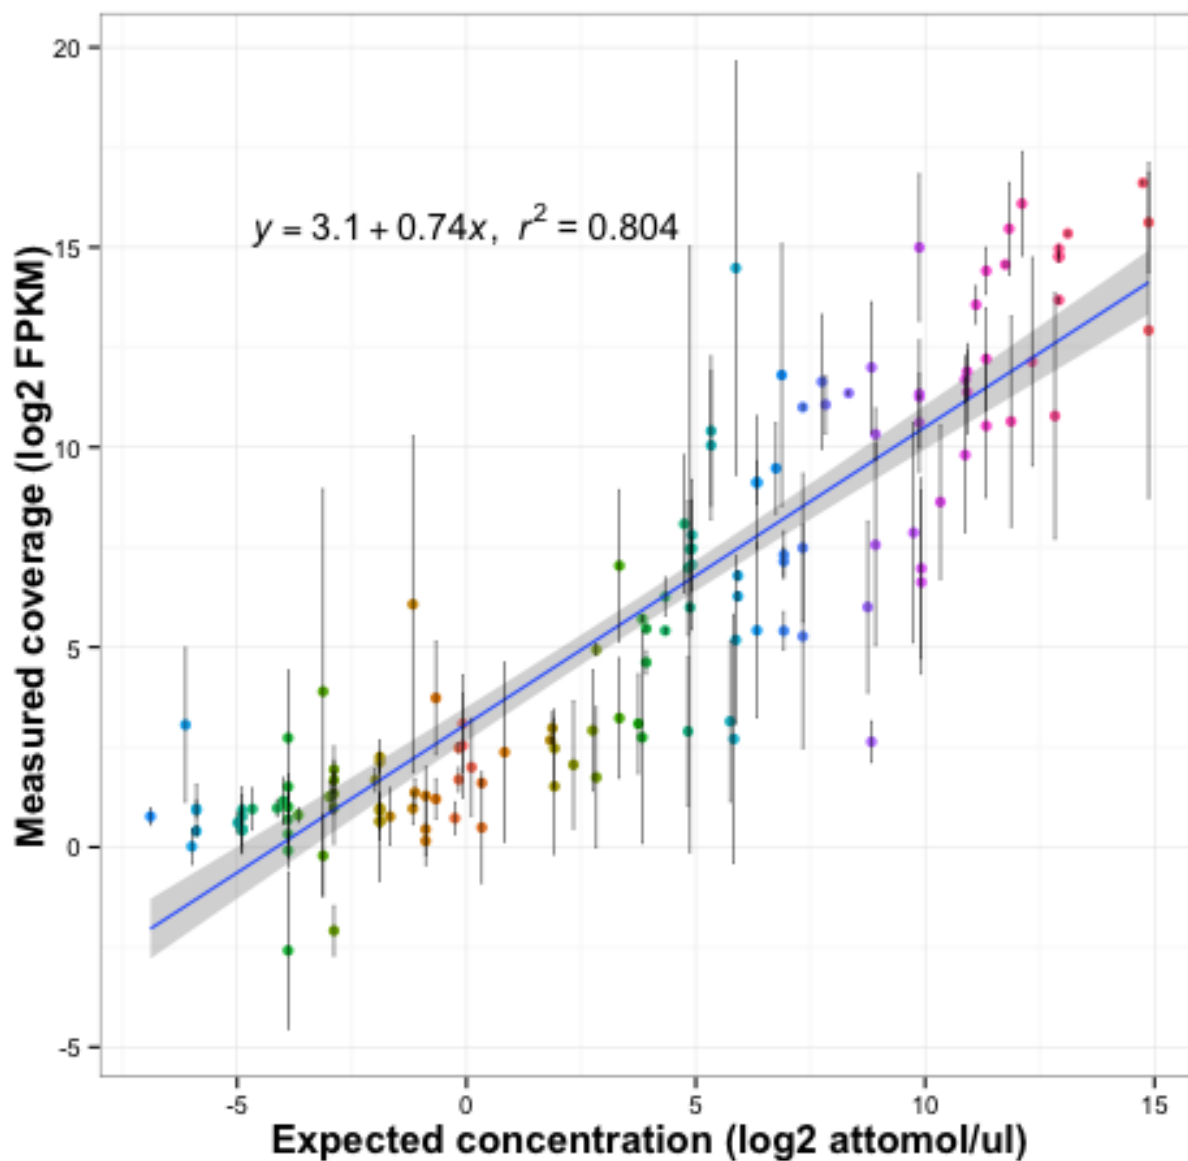

### Minor/Major plot

The Minor/Major plot shows the relative quantification of alternative spliced isoforms by measuring the minimum isoform as a fraction of the major isoform for each sequin gene. The accuracy of the quantification is typically dependent on sequence coverage and higher for high abundance genes. The concentration of the gene is shown by colors.

## Pooled scatter plot for isoform expression

The pooled scatter plot shows the expected abundance against measured abundance on the logarithm scale for all the replicates. This is done by plotting the average and standard deviation. The line is the fitted linear regression with 95% confidence interval drawn in black. A high  $R^2$  is desirable; the higher it is, the more accurate the isoform expression experiment is.

## Isoform expression summary

## Isoform expression scatter plot for: A1

The scatter plot shows the relationship between expected abundance against measured abundance on the logarithm scale for a single replicate. The line is the fitted linear regression with 95% confidence interval drawn in black. A high R2 is desirable; the higher it is, the more accurate the isoform expression experiment is.

## Scatter plot

The scatter plot shows the expected fold-change of genes against their measured fold-change. The more correlated they are the more accurate the experiment is. The R<sup>2</sup> statistic measures how accurate the experiment is in detecting fold-changes. Accurate detection of fold-changes is crucial for differential analysis. The accuracy of the quantification is typically dependent on abundance and higher for high abundance genes. The concentration of the gene is shown by colors.

## ROC plot

When true differences in expression exist between samples in an experiment, those differences should be detected in differential expression tests; where no differences exist, no difference should be detected. The true-positive and true-negative sequins controls can be used in a receiver operator characteristic (ROC) curve analysis of rank ordered differential expression test P-values.

## MA plot

The MA plot is used to study dependences between the log fold-ratio and the average normalized counts. The counts are normalized as they are adjusted for the library size. Typically, the variability is higher for less abundance genes.

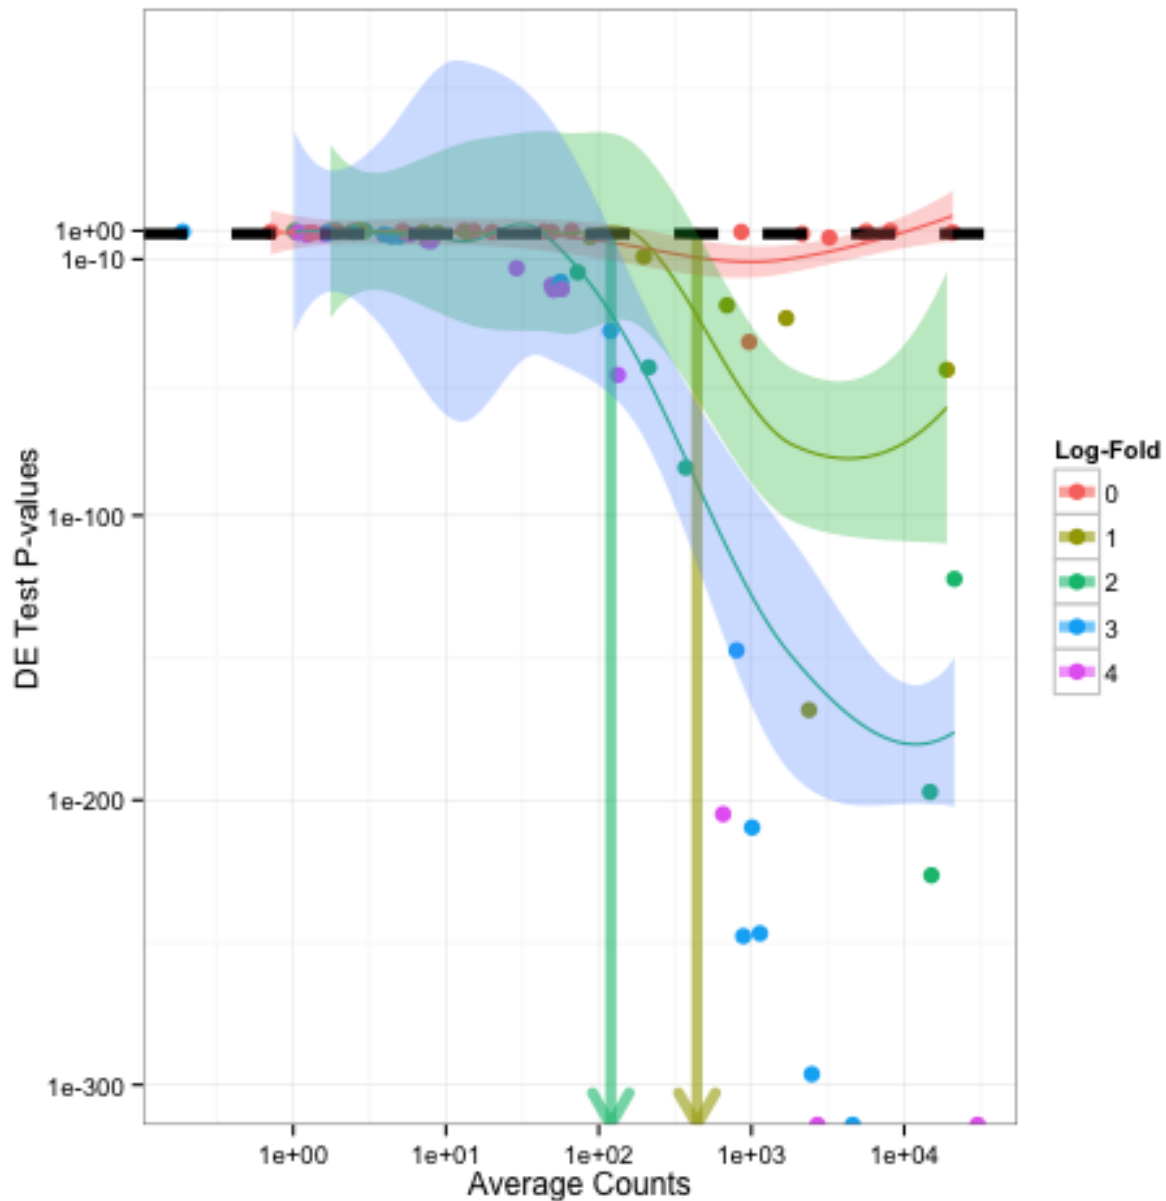

Sequin data points are colored by log-ratio. They represent the mean log-fold changes for a given concentration level. Endogenous genes data points are shown as pink points.

## LODR plot

Identifying differentially expressed genes is the objective of differential expression experiments; however, how much information is needed to have confidence that a given fold change in expression of transcripts will be detected? The LODR estimates can inform researchers of diagnostic power at a given fold change.

An LODR estimate for a particular fold change is the minimum signal, above which differentially expressed transcripts can be detected with a specified degree of confidence. The estimate for each ratio group is found based on the intersection of the model upper confidence interval upper bound with the P-value threshold.

## Appendix: Sequin Alignment
